

2. Performance degrades as worker count increases for both approaches. Threads increase from 4.6s to 5.6s. Processes worsen significantly from 4.7s to 11.6s. Single worker is fastest for both.

3. The Linux VM has limited CPU cores, 1 or 2. With insufficient cores, adding workers creates overhead without parallelization benefit. Thread context switching and GC contention increase execution time. Processes suffer more due to spawn overhead and IPC costs.
